**SUMMARY**

Bruce Perry from Toronto holds a small claim group twelve kilometres north of Princeton in a favourable setting for alkali porphyry copper gold deposits. The property covers the western part of the Bromley Pluton in contact with Nicola Group volcanics and sediments (Eastern Facies). Limited previous sampling on the property produced significant copper values with associated gold and silver from strongly altered and fractured Nicola sediments, volcanics.

Three days were spent by Placer Dome mapping and sampling on the property in June and July 1991. The main Cu showing at the Freddy B trench features copper (malachite and chalcopyrite) mineralization in strongly altered sediments (chlorite, silica, hematite, potassic with gypsum and carbonate veins) possibly associated with a monzonitic dyke. A 60 metre section of these rocks in the trench yielded copper values up to 0.4% with anomalous gold (to 165 ppb), zinc (to 0.1%) and molybdenum (to 306 ppm). Similar copper, gold (to 505 ppb Au) mineralization occurs in two very old adits 500 metres to the south.

There are very few other outcrops in the showing area, none to the north. To the south a number of small alkalic plugs and dykes intrude Nicola volcanics. Copper mineralization in more fractured and propylitically altered volcanics produced values up to 2% Cu.

Previous mapping in the area did not indicate these alkalic intrusives. A northerly trending belt of copper mineralization along Hayes Creek 600 metres long by 200 metres wide is possibly associated with these intrusions and an earlier structure. This property, although small, deserves further work to evaluate the extent of intrusive rocks and copper-gold mineralization.
1.0 INTRODUCTION

Bruce Perry holds a small copper gold property, the Danny 1 on Hayes Creek, north of Princeton in Similkameen Mining Division. In June and July 1991 Placer Dome personnel spent a total of three days on the property conducting preliminary geological, prospecting and sampling programs. This work is being filed on the Danny 1 claim for assessment credit.

1.1 Location and Access

The property lies at the junction of Hayes and Collett Creeks ten kilometres northeast of Princeton and is covered by NTS sheet 92H-9. The property location is shown on Figure 1.

Access is by paved highway from Princeton past Jura to Hayes Creek (15 kilometres), then south by a network of gravel roads and trails onto the property. Access to the area east of Hayes Creek is more difficult and requires a river crossing or a lengthy hike.
1.2 Property

The property consists of a single claim, the Danny 1, totalling six units located in Similkameen Mining Division.

</table>

Bruce Perry of Toronto is the recorded property owner. Originally the property consisted of a single reverted crown grant the Freddy B (Record No. 3640) which Perry acquired in a B.C. government auction in 1990. Subsequently the Freddy B was overstaked by the Danny 1 in 1990 and incorporated by forfeiture in March 1991.

The Danny 1 claim over stakes the southwestern corner of the pre-existing GW 2 claim north of Collett Creek. This overstaking reduces the size of Danny 1 to approximately 5 units as shown in Figure 2.

1.3 Physiography and vegetation

The property covers a section of Hayes Creek where it has cut a fairly deep and steep sided valley into gently rolling topography. Elevations range from 730 to 860 metres.

Gravel terraces and bedrock cliffs occur along the river with fairly thick stands of mature fir and pine, and thick underbrush. Above, cleared pasture is interspersed with fairly open stands of largely second growth fir and pine.

PROPERTY LOCATIONS
1.4 History and Previous Work

Work on the Freddy B claim dates back to the turn of the century. Numerous old workings are evident on the property in the form of caved trenches and adits along the western side of Hayes Creek. A summary of previous work on the Freddy B follows:

1908

1915
Mention of two short adits in strongly altered and schistose sediments. Disseminated copper mineralization was noted in both adits 'upwards of 50 feet in width'. Stronger copper mineralization was noted in the more northerly adit. The property was judged to 'possess sufficient merit to warrant being thoroughly and systematically prospected by diamond drill boring'. B.C. Ann. Report 1915.

1973
Prospecting Report (No. 6157). Three areas on the Freddy B near Collett Creek produced copper values in the 0.15% to 0.3% range (unknown width).

1990
Samples taken by B. Perry from the Freddy B trench and area to the south yielded strongly anomalous copper values up to 3.51% with gold to 320 ppb and silver to 23.7 gt.

1.5 Regional Geology and Mineralization

The property lies within the Quesnel Terrane near the intersection between the northerly trending Boundary and Summer Creek Fault systems at the northeastern edge of the Princeton Basin.
(Figure 3). This is a complex structural area with Mesozoic and Tertiary elements as well as numerous intrusive events involving the Bromley (Triassic-Jurassic), Osprey Lake (Late Jurassic) batholiths and Summers Creek (Cretaceous) stocks. A fault wedge of Nicola volcanic (Eastern Facies) and sedimentary rocks separates the Bromley and Osprey batholiths from the Tertiary volcanics and sediments (Princeton Group) within the Princeton Basin to the east (Tertiary age sedimentary-volcanic, transtensional basin).

In the Princeton-Aspen Grove Belt a number of copper porphyry deposits and occurrences (plus or minus gold) occur along the Boundary-Summer Creek fault systems including Copper Mountain-Ingerbelle (Similco), Axe and Man. Compilations indicate that northwesterly trending tentional zones along the fault system are preferential sites for alkalic intrusions. The Freddy B lies at the south end of one of these zones which extends to Allison Lake and hosts copper-precious metal mineralization on the Lucky and Mac-Boch properties (Figure 2).
### Legend to Figure 3

**Triassic and/or Jurassic**
- Late Triassic and/or Early Jurassic
  - Granodiorite (gd) (Allison Lake Bromeley, Cahill Creek, parts of Mount Lytton Complex)
  - Small diorite plutons in Nicola Group, diorite and amphibolite of Mount Lytton Complex, diorite Hedley Intrusions
  - Alkaline intrusions, syenite (s), diorite (d) (Copper Mountain Stock), syenodiorite (sd), gabro (gb) and ultramafic rock (u) (Tulameen Complex)
  - Cultus Formation: argillite, sandstone, minor carbonate
  - Late Triassic
    - Nicola Group
      - Volcanics, undifferentiated mafic to felsic volcanics and minor argillite
      - Western volcanic lacies of Nicola Group, felsic to intermediate pyroclastics, argillite, local carbonate
      - Central volcanic lacies of Nicola Group, intermediate, feldspar and feldspar augite porphyry pyroclastics and flows
      - Eastern volcanic lacies of Nicola Group, mafic augite and amphibole porphyry pyroclastics and flows
      - Sedimentary lacies of Nicola Group, argillite, sandstone, till and local mainly carbonate clast breccia and conglomerate
      - Amphibolite, foliated diorite, mylonite and chlorite schist and minor marble derived from Nicola Group
  - Triassic
    - Camp Cove Formation: silicic argillite, mafic volcanics
    - Spider Peak Formation: mafic volcanics
    - Granite-gneiss of Hornet Creek
    - Carbonate in Mount Lytton Complex
    - Copburn schist, meta chert, para amphibolite, mafic ultramafic rock, possible correlative of Hozameen-Bridge River Complexes, metamorphosed in Cretaceous
    - Ultramafic rock, local gabbror

**Permain to Jurassic**
- Hozameen Complex (PjH, Pjhw)
  - Undifferentiated, chert, diabase, mafic volcanics, mafic gabbro, and ultramafic rock

**Jurassic**
- Bridge River Complex
  - Silicic and chlorite schist: phylite, correlative of Hozameen Complex but west of Fraser River
  - Ultramafic rock and local gabbror, associated with Hozameen and Bridge River Complexes

**Ordovician to Triassic**
- Apex Mountain Complex
  - Argillite, chert, mafic volcanics, meta gabbro and associated mafic volcanics
  - Includes Braggshaw Independent, Assiniboine, and Sunburst Intrusions
Fig. 3: HAYES CREEK AREA COMPILATION MAP

GEOLOGY
2.0 PROPERTY GEOLOGY AND MINERALIZATION

2.1 Introduction

During June and July a total of three days were spent by Placer Dome personnel on the Danny I Property. This work was under the supervision of R.C. Wells (Consulting Geologist). A detailed examination including chip sampling was made of the Freddy B trench (Figure 6). Preliminary geological mapping was conducted over the area west of Hayes Creek, using air photograph control (Figure 4).

2.2 Distribution

The Danny Property covers the western edge of the Bromley Pluton (granodiorite to diorite) in contact with northerly striking Eastern Facies, Nicola Group volcanics and sediments. In detail, the property geology is quite complex with a variety of felsic intrusives. The Nicola sediments on GSC Map 41-1989 are far more restricted than indicated. Much of the area is underlain by andesitic volcanic flows.

Much of the northern part of the property is overburden covered with widespread gravel deposits along Hayes Creek. Bedrock exposures are common but generally small in the southern and western areas, mainly on steeper slopes and along the creek.

2.3 Lithology

A number of different rock units could be distinguished during the geological mapping. The distribution of these is shown on Figure 4. The units are as follows:
NICOLA GROUP VOLCANICS AND SEDIMENTS

1. Mafic Volcanic Flows and Minor Fragmental Units.

Massive, medium to dark green, fine grained, andesitic flows predominate. Locally there is evidence of narrow interflow fragmental units and flow breccias. These units appear to have a northerly strike.

2. Chloritic, Hematite Altered Sediments.

These rocks are poorly exposed along Hayes Creek, original textures are obscured by chloritic and hematitic alteration and deformation. Cut slabs of these brown to grey coloured rocks indicate crude bedding in (probable) sandstones and argillites.

INTRUSIVE ROCKS

These are mainly feldspar porphyries of variable colour and grain size. Whole rock analyses was used as an aid in distinguishing intrusive rock type. This data was plotted on a standard alkali-silica diagram (Figure 5). Sample points lie predominantly within the alkali field (Irvine and Barager 1971).

3. Feldspar Porphyry-Syenodiorite

An outcrop of pinkish grey leucocratic feldspar porphyry occurs 200 metres south of the Freddy B trench. White tabular and locally zoned plagioclase phenocrysts up to 3 mm long lie in a fine to medium grained groundmass with plagioclase, orthoclase and less than 5% chloritically altered mafics (after pyroxene?). Hematitic alteration is common and locally strong.
4. **Mafic Feldspar Porphyry-Diorite to Syenodiorite.**

Medium grey and white speckled, feldspar porphyry intrusives outcrop near the southern claim boundary. These are diorites with 10 to 20% white plagioclase phenocrysts that are locally zoned, generally subhedral and less than 2mm long. The groundmass is fine to medium grained and dark coloured with minor plagioclase.

5. **Pink Monzonite to Quartz Monzonite**

These are pink to grey, leucocratic, medium to coarse grained locally feldspar porphyritic monzonites and quartz monzonites. Plagioclase feldspars predominate with some potassic feldspar and generally less than 10% quartz. Mafic minerals occur in small amounts and are commonly altered to chlorite.

The more alkalic intrusives, Units 3 and 5 are compositionally quite different from the Bromley and Osprey plutons. Unit 4 the mafic diorite may represent a marginal phase of the Bromley pluton west of Hayes Creek.
FIGURE 5  ALKALI-SILICA DIAGRAM
DANNY 1 PROPERTY

ALK/S-ALK

SiO2(%)  AVERAGE ROCK TYPE (DALY)

IRVINE AND BARAGAR (1971) FIELDS FOR ALKALINE, SUB-ALKALINE
2.4 Structure

The northerly trending contact between the Bromley Pluton and the Nicola rocks lies close to Hayes Creek. At the Freddy B trench and the old adits to the south there is evidence for a structural zone with similar trend along Hayes Creek. This fracturing is fairly strong in the Nicola sediments and volcanics but appears to predate (in part) and to an extent control intrusive activity. Some monzonite dykes (Unit 5) clearly follow parallel structures, others transect them.

2.5 Metamorphism

On the property metamorphic grade varies with distance from intrusions. Close to the intrusions in particular the syenodiorite (Unit 3) volcanics are converted to coarser grained biotite hornfels.
DESCRIPTION

Feldspar Porphyry. Light pink phenocrysts to 4cm in f.y. hemitic, siliceous groundmass. Moderately jointed 5-30cm spacing. Mal on some joints/fractures. Petchy t.diss. py, opy.

Mixed browns, greens, grey, strongly fractured and altered. Abundant gypsum on fractures.

Mod to strongly fractured, granular textures (seds?). Much mal. Rusty limonitic zone with some quartz.

Moderate to strong fracturing with gypsum. Local mal.

Kspar zone 10-20cm wide 10/65 has gypsum along fractures (veinlets).

Pink grey strongly fractured, much gypsum veinlets, mal. hem. Local kspal alteration.

Prominent fracture set 2-20cm spacing. Strongly fractured with gypsum veinlets, much malachite.
associated with more fractured and propylitically altered (chlorite, carbonate, hematite, local epidote) volcanics. Grab samples from these showings have yielded copper values up to 2.2% and silver to 10.6 gt (elevated Bi).

Patchy hematite, chlorite and silica alteration was noted in the intrusive rocks and appears to be strongest in the syenodiorite (Unit 3) and some monzonite dykes (Unit 5). Fine to medium grained disseminated pyrite is widespread in the more mafic intrusives (Unit 4) and locally in the volcanics and sediments.
CONCLUSIONS AND RECOMMENDATIONS

The Danny I property covers Nicola Group volcanics and sediments intruded by several alkalic monzonite to syenodiorite dykes and plugs.

Copper mineralization with associated gold and silver values occur in fractured and strongly altered Nicola rocks proximal to the alkalic intrusives.

Limited recent geological mapping and prospecting has identified a northerly trending belt along Hayes Creek of copper showings and old workings, 600 metres long by 200 metres wide.

Due to overburden cover it is very difficult to estimate the true width of copper-gold mineralization in the Freddy B trench area. Upwards of 50 feet of copper mineralization has been documented from the old adits 450 metres to the south.

Diamond drilling in the trench area would yield valuable information on the width, grade and controls on the copper-gold mineralization and is recommended.

STATEMENT OF QUALIFICATIONS

I, RONALD C. WELLS of the City of Kamloops, British Columbia do hereby certify that:

1. I am a Fellow of the Geological Association of Canada.

2. I am a graduate of the University of Wales, U.K. B.Sc in Geology (1974), did post graduate (M.Sc) studies at Laurentian University, Sudbury, Ontario (1976-77) in Geology.

3. I am presently employed as a consulting geologist based in Kamloops.

4. I have practised continuously as a geologist for more than 12 years throughout Canada and the U.S. Previous to this experience and employment as a geologist in Europe.

1985-1990 Regional Geologist for Southern B.C. Kamloops Office Corona (Lacana) Corporation

1980-1985 Regional Geologist Abitibi Greenstone Belt Kirkland Lake Office Lacana Mining Corporation Toronto, Ontario

5. That I have no interest, direct or indirect, in the property discussed in this report, nor do I expect to receive any.
APPENDIX A

SAMPLING AND ANALYTICAL PROCEDURES
SAMPLING PROCEDURES

1. CHIP SAMPLING

At the Freddy B Trench chip samples were taken using hammer and where necessary chisel. These were large samples between 5 and 10 kg and basically chip-panels with an average sample width/height of 1.5m.

2. GRAB SAMPLES

Again, fairly large samples averaging 5 kg.

3. WHOLE ROCK SAMPLES

Samples for whole rock analysis were carefully taken avoiding veined and altered material.

ANALYTICAL PROCEDURES

All rock samples were taken to Eco Tech Laboratories Ltd. in Kamloops B.C. The laboratory methods are summarized in the following tables. Certificates of analysis are available in Appendix B. Map sample location numbers have been added to these.
GEOCHEMICAL LABORATORY METHODS

SAMPLE PREPARATION (STANDARD)

1. Soil or Sediment: Samples are dried and then sieved through 80 mesh nylon sieves.

2. Rock, Core: Samples dried (if necessary), crushed, riffled to pulp size and pulverized to approximately -140 mesh.

METHODS OF ANALYSIS

All methods have either known or in-house standards carried through entire procedure to ensure validity of results.

1. Multi-Element Cd, Cr, Co, Cu, Fe (acid soluble), Pb, Mn, Ni, Ag, Zn, Mo

   Digestion          Finish
   Hot aqua-regia     Atomic Absorption, background correction applied where appropriate

WHOLE ROCK ANALYSIS

PROCEDURE:
1. Preheat muffler to 1050°C.
2. Weigh 0.10 g of sample into a test tube.
3. Add 0.50 g of Lithium Metaborate (LiBO₂).
4. Vortex.
5. Transfer samples to graphite crucibles.
6. Fuse samples for 30 minutes.
   - While samples are fusing - prepare plastic containers by adding 100 ml of 4% HNO₃.
7. After samples are fused, pour them into the labelled plastic containers.
8. Shake on the soil shaker for 30 minutes or until sample is dissolved, some black residue (graphite) will remain.
9. Make sure the silica is dissolved (silica looks cloudy and slimy).
10. ** Add 1 ml Hydrofluoric Acid (HF). Swirl.
    - Add 4 ml of 30% Boric Acid (H₃BO₃). Swirl and let sit a few minutes.
    - Be sure to prepare a blank with the same acid matrix as the samples.

REAGENTS:
- Lithium Metaborate (LiBO₂)
- Hydrofluoric Acid (HF)
- 30% Boric Acid (H₃BO₃)
  (Prepare Boric Acid ahead of time - it takes awhile to dissolve).

ICP SET UP:

<td></td>
</tr>
</tbody>
</table>
Measure HF using plastic test tube, don't let it come in contact with glassware.

Be sure samples are vortexed before transferring to graphite crucibles.

Make sure samples have been fused properly.

Be sure to replace all tubing and clean the spray chamber, nebulizer and torch completely after analysis. (Rinse with reagent alcohol then plenty of distilled H₂O and blow dry)

All the percentages added together for each sample should equal 100%. If results are out +/- 10% the numbers can be adjusted. If results are out by more than 10% - run again.
L.O.I. - LOSS ON IGNITION

PROCEDURE:

Preheat muffle to 1050°C.

Put weigh boats in preheated muffle for 20 minutes to burn off any volatile residue and put in desicator till the boats have gone back to room temperature (approximately 2 hours).

Record the weight of the boat, add approximately 1.0 grams of sample - weigh again and record. (use analytical balance to nearest .0001 g)

DO NOT TOUCH THE WEIGH BOATS WITH YOUR HANDS.

Put in preheated muffle for 1 hour.

Transfer to desicator - put the lid on but leave a small opening so the vacuum effect isn't too strong. Leave for the same length of time as the first weigh.

Weigh samples.

** Always use the same desicator **

CALCULATION:

\[
\text{wt. of Boat & Sample - wt. after Ignition} \times 100\% = \% \text{ LOSS ON Sample Wt. IGNITION}
\]
